What is WinOS?

WinOS is the first member of **The Windroid Project**. The project aims to *build a fully open-source and secure ecosystem containing operating systems, utilities, applications, games, and other software*. The first AI-assisted implementation of WinOS was **WinOS-Dev**. However, the actual WinOS implementation is planned to be built entirely by me, with *entirely different plans for the mainstream OS*.

WinOS is an operating system designed around the idea that **the user is the final authority over what happens on their machine**. Through the **App Permission Manager (APM)** and **Windroid Security**, the *user has control over permissions and interactions between applications and system components*.

A major goal of **WinOS** is **user privacy and anonymity**. WinOS should not rely on unnecessary background applications or services running without the user's knowledge or permission.

Unlike many traditional operating systems, *the core of WinOS is intentionally **minimal***. The **WinOS System** provides the fundamental functionality required to operate the machine, while higher-level functionality is provided through **ESP Apps** and other system components.This means that *WinOS can remain a small and relatively simple foundation while still becoming a complete, Windows-like desktop operating system through replaceable system applications and frameworks — without requiring unnecessary built-in bloat*.

Core Philosophy

WinOS follows a simple principle:

The user is king.

The operating system should provide the user with *control* rather than silently making decisions on their behalf. The architecture therefore separates the minimal **WinOS System** from higher-level functionality such as the desktop, settings, file management, drivers, and other system applications. *This allows the system to remain minimal while still being extensible*.

The WinOS Project

The whole WinOS project consists of four main parts:

- **WinOS-EFI** — the UEFI bootloader implementation responsible for bringing WinOS into UEFI-based systems and loading the WinOS System.
- **WinOS-Kernel** — the **WinOS System** itself. It contains WinOS' core functionality, including its security model **Windroid Security**, the **App Permission Manager (APM)**, basic permission management, fundamental hardware and device discovery,

memory and process management, and basic rendering through the Software Renderer.

- **WinOS-Editor** — the development environment primarily intended for creating **ESP (EFI System Partition) System Framework Apps** and other system-level components of WinOS.
- **WinOS Studio** — the public-facing development environment intended for creating **system and user applications**, particularly GUI applications for WinOS.

Together, these four components form the *foundation of the **WinOS** platform*.
